Trajectory inference (pseudotemporal ordering)

- Pseudotime is an abstract unit of progress = the distance between a cell and the start of the trajectory

  → Pseudotime is a measure of how much progress an individual cell has made through a process **such as cell differentiation**

- In single-cell expression studies, captured cells might be widely distributed in terms of progress (Cells don't progress in synchrony!)

  → Ordering each cell according to its progress along a learned trajectory

Cancer Heterogeneity

Clonal Theory (Nowell 1976)

Founder cell

Time

Normal/ Healthy Cell

Tumor Population 1

Tumor Population 2

Tumor Population 3

Clonal Mutation (exist in all cancer cells)

Subclonal Mutations (exist in a subset of cancer cells)

Question

- If cancer samples are a mixture of different cells (e.g. cancer subtypes, tissues of origin), can we infer the stage and/or origin of cells from their evolutionary trajectory?

Approach

- **Datasets**
  - Ovarian cancer → subtype heterogeneity + tissue of origin
  - Head and neck cancer → primary vs metastasis
- **Tools**
  - Monocle3
  - Slingshot
  - Palantir
  - PAGA

Deliverables

- **Benchmark summary** ← Apply trajectory inference tools on different single-cell cancer samples
- **Analysis workflows**
- **Proposal on tool updates** *(e.g. what is the biological difference between differentiating cells and cancer cells need to be considered)*
